

— EDITION 38

Anatomy of an AI SDR that runs without me watching

*A demo proves the idea can work. A deploy
proves it works when nobody is watching.
Here is the wiring between the two.*

A 8-part breakdown

SWIPE >>>>

0101 / 08

| Demo versus deploy.

A demo runs while you watch and click. A deploy runs at 3am when you are asleep and something upstream has quietly changed. The gap is where the real work lives.

0202 / 08

| The webhook.

A lead arrives from the client's existing form.
A webhook catches it the instant it lands, with
no one in the loop. The front door has to be
always open.

0303 / 08

| The background worker.

The webhook does not do the work. It hands off to a worker, so the response is instant and the heavy lifting happens out of band. Slow work, fast front door.

0404 / 08

| The secrets.

Keys and credentials live outside the code, loaded at runtime. The build never carries them. A leaked repo is not a leaked system.

0505 / 08

| The health check.

A small endpoint that says I am alive. If it goes quiet, I know before the client does. Silence is a state I monitor, not one I assume away.

0606 / 08

| The failure path.

If my service is down, leads still land in the client's existing funnel, exactly as before. An outage degrades to the old normal instead of losing business.

0707 / 08

| Idempotency.

A retry must never act twice. The worker checks before it acts, so a redelivered lead is not a double action. This one came straight from payments.

0808 / 08

| Single-tenant on purpose.

One client, one deploy, one database. I did not build for tenants that did not exist, and that decision removed a whole class of work.

— THE TAKEAWAY

That is the distance between a demo and a **deploy.**
